% Comment on your observations comparing these two signals and their Fourier
% transforms
% Both signals seem to have similar amplitudes in across the
% frequency range. However, the phase angle see to vary differnently
% between the two. The second time shifted unit step function seem to
% always stay positive in the u(t+5)-u(t-5) unlike u(t)-u(t-10) where it
% seems to be positibe at the negative frequencies and negative in the
% positibev frequenies. Additionally, it seems to be dropping by 2 radians
% at a time linearly before going back to the original after the drop finishes
% in
% the u(t)-u(t-10) unlike u(t+5)-u(t-5) where the jumps seem to happen
% discretly, behaving like unit step functions.

```

% Comment on your observations. Is there a certain trend you see when
    increasing #?
% Yes, it seems like the fourier transformation magnitude plot is getting
    narrower and
% narrower as sigma increases, with a fixed peak value of 1. As for the
% function in the time domain, the opposite behavior is occurring where the
% plot continuously gets wider with a decreasing peak limit.
```

Pick a different Fourier transform pair and do the previous time scaling demonstration for it as well.
